TITLE: The Characteristics of the Fuel Supply by Pumps with a Distributor (Osobennosti podachi topliva nasosami s raspredelitelem)

PERIODICAL: Avtomobil'naya promyshlennost', 1958, Nr 7, pp 6-8 (USSR)

ABSTRACT: In its development of the ON-2 fuel feed pump with a distributor, NATI has changed the scheme of the high pressure line by changing over the delivery valve from the cavity above the plunger pair to the distributor (Fig. 2b). The amount of fuel over the valve in the distributor has been reduced to a minimum. Further design changes of the ONM pump devised by NATI-NZTA (Fig. 5) (as compared with the single-plunger EKB fuel pump designed by the Kotlyarenko brothers and G.B. Bartulli (Fig. 4)) provide a complete removal of the remaining pressure of both line sectors of high pressure. This was found to be the most effective arrangement. There are 2 graphs, 4 diagrams, 1 oscillogram and 1 Soviet reference.

TITLE: Regulator of the Fuel Pump American Bosch (Regulator toplivnogo nasosa Ameriken Bosch)

PERIODICAL: Avtomobil'naya Promyshlennost', 1953, Nr 3, pp 43-44 (USSR)

ABSTRACT: The mechanical fuel pumps for diesel engines have the following drawbacks: the great stress on the foot lever causes driver fatigue; during work at high speed ranges, the degree of irregularity is increased sharply. Measures were tried to avoid these drawbacks. The stress on the foot lever is reduced by indirect action on the spring of the regulator. The irregularity in the work at high speeds, is reduced by a combination of springs. In Soviet engine manufacturing, such a system is used in the fuel pump of the engine 4Ch 8.5 and the same device is used in the fuel pumps of "American Bosch". Figure 2 shows the position of the spring in correspondence to the regulator lever. The tests of the fuel pump of the American Bosch show that irregularity, even at a considerable change of speed is slight. According to the author, the pump has the drawback that the elements of regulation and the spring may be damaged during operation.

TITLE:

Research on Distribution Type Fuel Pumps (Issledovaniye toplivnykh nasosov raspredelitel'nogo tipa)

PERIODICAL:

Avtomobil'naya promyshlennost', 1958, Nr 6, pp 26-29 (USSR)

ABSTRACT:

The authors describe in detail the distribution type PSA and PSB fuel pumps, constructed by the US firm of American Bosch. The NATI laboratory made an extensive research on two of such pumps; PSB-4A for 4 cylinders and PSB-6A for six cylinders engines. Conclusions made in regard to their dimensions and weight show that these pumps are not as good as other known foreign distribution type pumps. There are 7 graphs, 3 diagrams, 1 table and 4 non-Soviet references.

M

Local Spectral Analysis in Solving Some Metallurgical Problems. V. I. Danilov and A. M. Zubko (Zavod. Lab., 1945, 11, 672-680; C. Ab., 1944, 40, 2755).—[In Russian]. Methods for the analysis of non-metallic inclusions in metals and of liquation non-uniformity of steel are discussed.

Scattering of x-rays in an acetone-water solution. V. I. Danilov, I. M. Zubko, and A. I. Danilova. *Zhur. Eksppl. Teorii. Fiz.* 19, 142-6(1949). In pure H₂O at room temp., with Ag and Cu radiation, max. are found at $\sin \theta/\lambda = 0.10, 0.23, 0.25$, and 0.50. The curve for pure Me₂CO has peak at about 0.12; in the range 0.2-0.3, where the H₂O curve has its 2nd max., the Me₂CO curve shows a uniform decrease of intensity. The curve of a soln. Me₂CO:H₂O = 1:2.5 mol. shows the peak of Me₂CO at 0.12 and a hint of a max. between 0.2 and 0.3, i.e. in the region of the 2nd max. of H₂O, and 2 further max. in the ranges 0.3-0.4 and 0.5-0.6. Consequently, there is no simple additive superposition at small $\sin \theta/\lambda$ up to about 0.2, but above 0.2 there is additivity. This is

consistent with the presence, in the soln., of small areas with a structure close to that of the pure components.

542. Scattering of X-rays in an extended-molecule solution. Dugrov, V. I., Zharov, A. M. and Danilova, A. I. *J. Exp. Theor. Phys.*, USSR, 19, 243-50 (Moscow, 1949) in Russian.--There are considerable differences in the results of diffraction studies by various authors of this solution, as well as of comparable solutions (e.g. benzol, cyclohexane), and they mainly concern the question whether or not a superposition of the patterns due to the single components takes place. The fact that the first maxima of either coagulant appeared separately, led Ward (Amer. J. Phys. 177 (1934)), and after him Moshkov (Dissertation Univ. Fiz. (1938)), to conclude that the superposition principle did not apply unreservedly. A later check on Ward's data by Eusemann and Gengrich (Amer. J. Phys. 2155 (1942)) proved them to be incorrect, at the later authors found superposition already for the first maximum. The paper gives a detailed report on a repetition of Moshkov's experiments in monochromatic reflection, in order to clarify the question whether an

unambiguous structural analysis of solutions is possible at all in spite of the well-known "superposition" appearance of the diffraction pictures. The results are discussed, referring to work of many researchers on this subject, and to the individual diffraction curves of the components, and it is shown that the ratio $(\text{b}_1 + \text{b}_2)/\text{A}$ decides whether or not superposition takes place. Up to a value of 0.2 of this ratio, there is no superposition, whether it is single or double above this value. The conclusion reached is that in solution there are always small regions of a structure similar to the structure of the individual components. This is also supported by a comparison with Bernal and Fowler's hypothesis on the structure of water (Amer. J. Phys. 3951 (1933)), especially by the quadrupole co-ordination of the molecules ensured by this theory.

Fine structure of active carbons. V. I. Danilov and A. M. Zubko. *Doklady Akad. Nauk S.S.R.* 22, 380-8 (1959).—The structures of a no. of carbons (activated, natural, or low-temp. cokes) were investigated by the method of integral analysis of x-ray intensity curves, yielding radial at. distribution functions which can be compared with various structure models. The results are plotted in the form of $4\pi R_p(R)$, where p is the d. (in atoms/ \AA^3) at the distance R , as a function of R . For an active C heated 20 hrs. in vacuo at 1000° , maxima are found at $R = 1.4$,

2.85, 4.1, and 5 \AA ; the area under the 1st max. is about 3, under the 2nd about 7 units; there is a sharp rise of the curve after the 2nd max. For different carbons, the positions of the maxima lie at the same R; these values coincide with the atom spacing in graphite lattices. Different carbons show different degrees of order, always increasing with the temp. of heating, and manifesting itself in a decreasing width of the maxima on the distribution curve and an increasing sign. of the 1st and 2nd max. from the rest of the curve. Further conclusions are obtained by comparison of the exp. distribution curves with theoretical curves calculated for definite models, specifically a lattice model with lattice dimensions of $\sim 14 \text{\AA}$, and blocks constituted as the 4×4 by 2 parallel lattices, oriented at any angle relative to each other, in contrast to the disposition in graphite crystals. Such a model gives a distribution curve similar to the exp. curve.

TITLE:

Concerning the Problem of Graphitization of Carbonaceous Substances (K voprosu o grafitizatsii uglevodlit'kikh veshchestv)

PERIODICAL:

Doklady AN SSSR, 1957, Vol. 114, Nr 6, pp. 1239-1241 (USSR)

ABSTRACT:

In coke samples which were burned at 1700 - 1800°C narrow lines situated at angles of 22°35' (intensive), 33° (weak) and 41°45' (intensive) occur in radiograms. As is seen in table 1 and figure 1, the position of these lines neither agrees with the lines of the α -modification of graphite nor with those of β -graphite. The nearness of these lines to the position of the graphite-lines caused some research-men to consider them as belonging to a special graphite modification (references 1 - 5). Then the authors give additional data from own investigations of the graphitization of the substances mentioned in the title. It was interesting to determine the nature of the non-carbon-diffraction lines which become visible in coke after a temperature of 1700 - 1800°C. Pure cane carbon alone and with small additions of iron oxide and silic dioxide were burned. The results

Card 1/2

Concerning the Problem of Graphitization of Carbonaceous Substances 20-114-6-28/54

(figure 2) showed that the above-mentioned lines belong to a solid α -solution of Si in Fe. As the position of the diffraction lines of this solid solution is very close to that of graphite, they may become a source of error in conclusions on graphitization. There are 2 figures and 7 references, 4 of which are Slavic.

TITLE: The Influence of Vacuum Melting on the Quality of Steel
(Vliyaniye vakuumnoy vyplavki na kachestvo stali)

PERIODICAL: Stal', 1958, nr 6, pp 520 - 525 (USSR).

ABSTRACT: An investigation of the influence of vacuum melting on the quality of Kh27 and 18KhNVA steels is described. Vacuum melting was carried out in a 12 kg furnace previously described (Ref 5). The conditions of melting and heating of liquid metal, teeming temperature and the time of retention in the final vacuo were the same for all melts. As a charge, mild steel ingots smelted in the usual manner in a 30-kg high-frequency furnace were used. The pressures used were: 1 mm and 1/10 of a metre, $5-8 \cdot 10^{-2}$ mm and $5 \cdot 10^{-5}$ mm. The results of chemical gas analysis and impact strength of steel Kh27 smelted under normal pressure and in vacuo - Table 1. The impact strength of forged and hardened-in-water from 900 °C metal from all heats was low. In order to find factors determining the impact strength of Kh27 steel, a series of vacuo heats using electrolytic materials were carried out. The results obtained showed that apparently the main element Card1/4 determining the impact strength is carbon. The influence of

SOV/133-58-6-15/35

The Influence of Vacuum Melting on the Quality of Steel

the depth of vacuo on the composition of metal, the gas content and the content of admixtures in steel is shown in Tables 2 and 3 and Figure 1, respectively. The influence of depth of vacuo on the mechanical properties of forged and thermally treated Kh27 steel - Table 4; the dependence of impact strength of the steel smelted in vacuo on the carbon content - Figure 2 and on the gas content - Figure 3. It is concluded that:
1) vacuum melting of Kh27 steel is accompanied by some changes in its chemical composition due to the evaporation of such elements as manganese and silicon and due to reactions forming gaseous products; 2) The change in chemical composition depends on the depth of vacuo; 3) Vacuum melting gives the following effects: a) the reaction between oxygen and carbon is more efficient; the content of carbon decreases to thousandths of parts of 1%; the reaction of sulphur with oxygen is also more intensive; b) the content of gas in the deoxidised metal decreases by a factor of 3; c) it has no influence on the structure of the metal. 4) On vacuum melting of steel Kh27 with its subsequent heat treatment, its impact strength can be considerably increased (30-60 times); the highest effect on the impact strength has the content of carbon;

Card 2/4

SOV/132-52-6-15/33

The Influence of Vacuum Melting on the Quality of Steel

when the latter is below 0.01%, the impact strength of steel reaches 15 - 18 kg/cm²; 5) On vacuum melting from electrolytic materials, the technological properties of steel Kh27 depend on the content of carbon and silicon. Steel 18KhNVA was made from a steel (C 0.19-0.20%) smelted from Sulinsk sponge iron. The experimental heats were carried out under normal pressure and a vacuo of 0.5 - 1 mm and 1.10⁻⁴ mm. The composition of steel %: C 0.14-0.21; Si 0.17-0.37; Mn 0.25-0.55; P, S < 0.035; W 0.80-1.20; Cr 1.35-1.65; Ni 4.00-4.50%. The gas content of metal from experimental heats in cast (nominator) and forged (denominator) state - Table 5; the amount of non-metallic inclusions - Table 6; mean indices of mechanical properties of longitudinal specimens from the experimental heats - Table 7. It is concluded: 1) That vacuum melting of 18KhNVA steel decreases the content of nitrogen and oxygen in steel: a) heats made at a vacuo of 10⁻⁴ mm contained many times less nitrogen (0.0020 - 0.0050%) than heats made under normal pressure (0.0030 - 0.010%); the influence of the depth of vacuo on nitrogen content was not detected; b) the content of oxygen in vacuo

Card 3/4

SOV/153-58-6-15/33

The Influence of Vacuum Melting on the Quality of Steel

heats at a pressure of 10^{-2} mm was on average 5 times smaller (0.0010 - 0.0028%) than in metal from heats made under normal pressure (0.0051 - 0.0140%); further decrease of pressure to 10^{-3} - 10^{-4} mm lead to a further decrease in the oxygen content (up to 0.0003 - 0.0005%). 2) Metal from vacuo heats contained 5-10 times less of non-metallic inclusions (0.0012 - 0.0058%) than the usual heats from industrial arc furnaces (0.0168 - 0.0281%) and possessed higher values for relative elongation (approximately by 40%) and impact strength (by 7 kg/cm²). There are 3 figures, 7 tables and 5 references, 3 of which are Soviet, 1 French and 1 English.

TITLE: Concerning the Coefficient of Friction and Specific Pressure in Hot-Rolling Under Vacuum

PERIODICAL: Stal', 1959, Nr 10, pp 929-931 (USSR)

ABSTRACT: Initial tests concerned the determination of the coefficient of friction and resistance to deformation in hot-rolling under vacuum. The experimental part of the work was carried out by Rudenko, V. A., and Shashkova, V. N. The coefficient of friction was analytically determined by the value of the forward slip which was, in turn, established by means of center punch indentations. Total pressure (P) was divided by the surface of the contact of the metal with roll (F) to obtain the resistance to deformation; i.e., specific pressure during rolling (p): $p = P/F$. Research conducted by radiographic method (Zemskiy, S. V., of Central Scientific Research Institute of Ferrous Metallurgy (TsNIIChM)) on carbon distribution in iron and nickel

SOV/133-5-9-10-14/39

The carbon concentration gradually increased, reaching its initial value at 2 mm depth. After vacuum rolling the carbon content on the surface somewhat exceeded the initial content. Ostensibly, an increased concentration of carbon should reduce the coefficient of friction during rolling [Ref 37]. However, the absence of oxygen has a greater effect than the slight increase in the quantity of carbon which promotes resistance to deformation during rolling. Although results are only preliminary they show that hot-rolling under vacuum is accompanied by increased coefficient of friction and resistance to deformation. One of the causes is, evidently, the redistribution of some elements observed at high temperatures and during deformation under vacuum. There are 4 figures and 5 Soviet references.

TITLE: Investigation of the Process of Hot Rolling of
Aluminium in Vacuum and in Air

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniya tekhnicheskikh
nauk, Metallurgiya i toplivo, 1961, No.2, pp.64-67

TEXT: The influence on the friction coefficient of scale or
an oxide film layer on the surface of a metal being rolled has been
the subject of numerous papers. However, no direct comparison was
made of the ordinary process of rolling aluminium in air and in
vacuum. Such a comparative study will permit direct elucidation
of the influence of oxide films on the conditions of rolling. The
authors investigated the power consumption, the speed and deforma-
tion conditions and the friction coefficient during hot rolling of
aluminium in vacuum and in air. The rolling was on TsNIIChermet
laboratory vacuum equipment permitting heating, rolling and
cooling of 15 x 20 mm, 200 mm long specimens in a vacuum down to
10⁻⁵ mm Hg. From a forged and annealed blank 150 x 10 x 12 mm

Card 1/5

4

specimens were cut. These were heated in a tubular electric furnace. The heating temperature was maintained within $\pm 15^{\circ}\text{C}$. Rolling was at 400°C with reductions of 20 to 70% per pass. The diameter of the rolls was 85 mm, the rolling speed 6.5 m/min. The rolls were of steel Wx-15 (ShKh-15) (hardness 55 R₁) and had a polished surface. The pressure was measured by wire strain gauges. Fig.1 shows a typical oscillogram in which 1 is the torque on the top spindle, 2 and 5 - pressure measured by the strain gauges, 3 - recorded roll speed, 4 - recorded strip speed, 6 - torque on the lower spindle, 7 - oscillation curve (500 c.p.s.). Fig.2 shows the dependence of the broadening $\psi = B_2/B_1$, % on the relative reduction $\Delta B/\Delta h$, where H , B_1 and L_1 are respectively the height, width and length of the specimens before rolling and h , B_2 and L_2 are respectively the height, width and length after rolling, $\Delta B = B_2 - B_1$ and $\Delta h = H - h$. (Here and in the following plots the dashed line curve refers to results obtained in vacuum and the continuous line curve refers to results obtained in air). Fig.3 shows the lead S_h as a function of the broadening,

Card 2/2

4

whereby

$$s_h = \frac{L_{strip} - L_{roll}}{L_{roll}} \quad (1)$$

where L_{strip} is the distance between the markings on the strip and L_{roll} is the distance between corresponding markings on the roll. Fig.4 shows the dependence of the specific pressure P , kg/mm^2 on the broadening ψ , %. Fig.5 shows the friction coefficient f' as a function of ψ , %. Fig.6 shows the torque M , kgm as a function of ψ , %. It was found that the friction coefficient and the required force, which depends directly on the friction coefficient, for vacuum hot rolling of titanium, grade BT-1 (VT-1), is considerably lower than for rolling in air, whilst for nickel and iron ($C - 0.01\%$) it is higher in the same way as it is for Al. This again confirms the dependence of these quantities on the chemical composition of the rolled metal. The following conclusions are arrived at:

1. It was established that for Al the coefficient of friction

Card 3/4

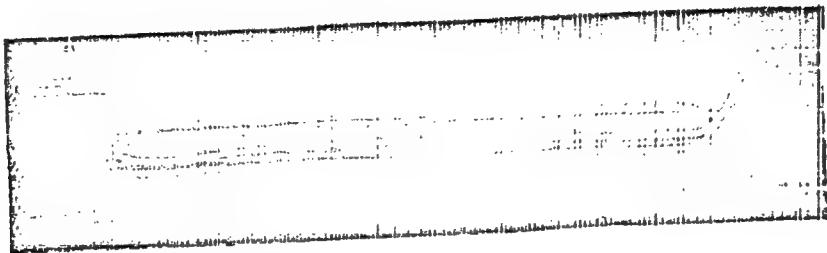

Investigation of the Process ...

20264
S/180/61/000/002/002/012
E073/E555

during rolling in vacuum is higher than for rolling in air, whereby the greatest difference (by a factor of about 1.4) was observed for smaller reductions;
2. it was confirmed that the friction coefficient during rolling decreases with increasing specific pressure both in air and in vacuum. There are 6 figures and 7 references: all Soviet.

TITLE: Investigation of some conditions of hot rolling of
titanium in vacuum and in air

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya
metallurgiya, 1961, No.6, pp.106-110

TEXT: The authors investigated the force, velocity and
deformation conditions during the process of rolling of titanium in
vacuum and compared the results with similar results obtained for
rolling in air. This was done to elucidate the influence of the
scale on the friction coefficient, specific pressure and other
parameters of the rolling of commercially pure titanium. From a
pre-forged blank, specimens 15 x 20 mm, 200 mm long were cut.
Those specimens which were to be rolled in vacuum (3×10^{-5} mm Hg)
were heated in a small-chamber electric furnace with molybdenum
heater filaments; those to be rolled in air were heated in an
electric furnace with nichrome heater filaments. The specimens
were rolled in the temperature range 800-1200°C on a two-high mill

Card 1/6

26582

Investigation of some conditions of ... S/148/61/000/006/006/013
E073/E535

with rolls of 85 mm diameter. The average reduction was 20%, the speed of rolling was 6.5 m/min. The rolls had a ground surface with a hardness of 55 RC. The rolling parameters, i.e. the total pressure, the torque, the speed of the rolled strip and the circumferential speed of the rolls were recorded by means of an 8-loop oscillograph. Fig.3 shows the dependence of the friction coefficient f'' and of the specific friction force t_s , kg/mm² on the rolling temperature, °C. Fig.4 shows the dependence of the friction coefficient f' and of the forward slip S_h on the rolling temperature, °C. Fig.5 shows the dependence of the specific pressure, kg/mm², on the rolling temperature, °C. Fig.6 gives the dependence of the specific pressure, kg/mm², and the friction coefficient f' on the reduction, %. In all these graphs the continuous line curves apply to rolling in air and the dashed line curves to rolling in vacuum. In the paper the authors apply three differing friction coefficients, one f'' determined according to the formula of S. I. Gubkin (Ref.12: Theory of shaping metals by pressure, Metallurgizdat, 1947), another f' determined on the basis of the theoretical formula for the torque, proposed by

Card 2/6

26582

Investigation of some conditions ... S/148/61/000/006/006/013
E073/E535

V. Bayukov and the third, f' , determined from the value of the forward slip. The following conclusions are arrived at:

1. In all cases of rolling in air the curve expressing the dependence of the friction coefficient on the temperature has a convex-shaped section with a maximum in the temperature range 1050-1150°C. If titanium is rolled in air at 800-1100°C, a dense layer of titanium dioxide scale forms which leads to an increase in sliding friction coefficient and spreading. At rolling temperatures above 1100°C, a dense layer of scale of a fine grain structure forms which peels off easily from the base metal and leads to a reduction of the friction coefficient; the friction coefficients f' and f'' are similar and their values are very near to each other. When rolling was performed in vacuum, the friction coefficient was considerably lower and showed a tendency to increase with increasing rolling temperature. This is attributed to a drop in the specific pressure with a minimum effect of other factors.

2. Changes in the specific pressure p and the specific friction force τ_s were similar during rolling in vacuum and in air. The

Card 3/6

26582

Investigation of some conditions ... S/148/61/000/006/006/013
E073/E535 X

values p and τ_s , and consequently also the torque, are affected by the sudden α to β transformations and this explains the sharp drop in the friction coefficient, forward slip and the slight increase in spreading in the temperature range 850-950°C.

3. With increasing reduction an increase is observed in the specific pressure and a decrease in the friction coefficient.

4. The experiments revealed considerable qualitative and quantitative differences in the force, velocity and geometrical factors pertaining to rolling titanium in vacuum and in air.

Experiments carried out earlier by some of the authors (Ref.14: Stal', 1959, No.10, 929-931) yielded differing results, namely, the coefficient of friction and the geometrical and force conditions depending on it were considerably higher in vacuum than in air in the case of rolling pure iron with a carbon content of 0.01%. This clearly indicates that the investigated quantities depend on the chemical composition of the rolled metal. There are 6 figures and 14 references: 13 Soviet and 1 non-Soviet.

TITLE: On the problem of the effect of vacuum melting and teeming upon the metal properties and the ingot quality

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 3, 1962, 41, abstract 3V258
("Sb. tr. In-t metalloved. i fiz. metallov Tsentr. n.-i. in-ta chernoy metallurgii", 1959, v. 6, 169-186)TEXT: At a TsNIICherMET pilot plant magnetically soft Fe-Co alloy K50F2 (K50F2) was melted in a high-frequency vacuum furnace; the alloy contains in %: > 0.05 C; > 0.2 Si; > 0.2 Mn, 49 - 51 Co; 1.5 - 2 V; > 0.5 Ni, > 0.025 S and P, the rest Fe. In the furnace space in cold state a vacuum was produced of the order of $1 \cdot 10^{-3}$ mm Hg. The heats were produced in ZrO_2 crucibles which were manufactured directly on the furnace. One crucible withstands > 40 heats. The melted ingots weigh 30 - 45 kg. In the vacuum-melted metal, the content of gas, non-metallic impurities and magnetic properties were determined. It was established that the melting of K50F2 alloy in a vacuum of 500 - 50 mm Hg was not accompanied by changes in the chemical composition of the alloy, except Si, whose

Card 1/2

On the problem of the effect ...

S/137/62/000/003/018/191
AC06/A101

amount decreased by 50%. The content of gases in the metal varies from 10 to 20 ml/100 g, instead of 60 ml/100 g contained in metal that was melted by conventional technology. The amount of non-metallic impurities in the alloy decreased substantially, and its magnetic properties are improved. Studies of the effect of vacuum melting and teeming of low-carbon nickel steel, containing 0.1 - 0.15% C and 2 - 3% Ni, on the formation of bubbles in the ingot, have shown that gas bubbles are formed during the teeming into vacuum molds of steel that had been subjected to short-time vacuum treatment in the ladle at 30 - 40 mm Hg pressure. Therefore teeming of metal that had been vacuum-treated in the ladle should be carried out in inert atmosphere.

Zubko, A. M.TITLE: Conditions during hot rolling in vacuum of various
pressures, in argon and in airSOURCE: Akademiya nauk SSSR. Institut metallurgii. Trudy, no. 9,
Moscow, 1962. Voprosy plasticheskoy deformatsii metalla,
105-108TEXT: The present work is a continuation of an earlier investiga-
tion by Ya. B. Gurevich and A. M. Zubko. The present authors stu-
died the effect of vacuum (10^{-1} - 10^{-5} mm Hg), of pure argon and
of air on the coefficient of friction, and on geometrical and force
parameters of rolling. The materials subjected to rolling were pure
iron and nickel. The rolling tests were carried out at 1100°C at
the rate of 6.5 m/min which produced 30% deformation. The rolling
mill was of the construction developed at the Khar'kov Physico-Technical Institute, AS UkrSSR (Khar'-
kov Physico-Technical Institute, AS UkrSSR) which had 85 mm dia-

meter rolls made of УХ15(ShKh15) steel. Vacuum was measured with a ВМТ-1(VIT-1) gauge. Samples were 150 mm long and 10 x 12 mm in cross-section. The coefficient of friction and the resistance to deformation rose in vacuum on decrease of pressure; in argon the coefficient of friction was the same as an $10^{-1} - 10^{-3}$ mm Hg vacuum. In air the coefficient of friction was the lowest. There are 2 figures.

D207/D308AUTHORS: Pavlov, I. M., Sigalov, Yu. M., Gurevich, Ya. B. and
Zubko, A. M.TITLE: On the temperature dependence of some hot-rolling para-
meters in vacuum and in airSOURCE: Akademiya nauk SSSR. Institut metallurgii. Trudy, no. 9,
Moscow, 1962. Voprosy plasticheskoy deformatsii metalla,
109-114TEXT: The present work is a continuation of an investigation by
the authors reported in the preceding paper (pp. 105 - 108 in the
present issue). Rolling tests were carried out on pure iron (0.01%
C) and nickel at temperatures of 800 - 1200°C using a ЦНИИЧМ
(TsNIICHM) rolling mill under the conditions described in the pre-
ceding paper. Temperature was measured with a thermocouple and an
ЛНР (SPR) potentiometer. The coefficient of friction of both iron
and nickel was lower in air than in 10⁻⁵ mm Hg vacuum. In air and
in vacuum the temperature dependence of the coefficient of friction

of iron had a maximum at 900°C, but in vacuum the friction passed also through a minimum at 1000°C and then rose with temperature. In the case of nickel the coefficient of friction fell with increase of temperature in vacuum, but in air there was a maximum at 900°C. The resistance of deformation and other rolling parameters varied with the atmosphere and temperature roughly in the same way as did the coefficient of friction. There are 6 figures.
